

Tbl — A Program to Format Tables†

L. L. Cherry

M. E. Lesk

Bell Laboratories
Murray Hill, New Jersey 07974

ABSTRACT

Tbl is a document formatting preprocessor for *troff* or *nroff* which makes even fairly complex tables easy to specify and enter. Tables are made up of columns which may be independently centered, right-adjusted, left-adjusted, or aligned by decimal points. Headings may be placed over single columns or groups of columns. A table entry may contain equations, or may consist of several rows of text. Horizontal or vertical lines may be drawn as desired in the table, and any table or element may be enclosed in a box. For example:

U. S. Energy Production/Consumption (in quadrillion Btu)			
Year	Production all sources	Consumption	Net
1953	36.77	36.27	+0.51
1958	38.81	40.35	-1.54
1963	45.85	48.32	-2.47
1968	56.81	61.00	-4.19
1973	62.06	74.28	-12.22
1978	61.01	78.09	-17.08
1983	61.19	70.05	-8.86
1987	64.55	76.01	-11.46

1. Introduction.

Tbl turns a simple description of a table into a *troff* or *troffnroff* reference(latest program (list of commands) that prints the table. It attempts to isolate a portion of a job that it can successfully handle and leave the remainder for other programs. Thus *tbl* may be used with the equation formatting program *eqn* reference(latest or various layout macro packages reference(latest msmacros) reference(lesk kernighan typesetting) reference(mashey smith documentation), but does not duplicate their functions.

This memorandum is divided into two parts. First we give the rules for preparing *tbl* input; then some examples are shown. The description of rules is

†This is a version of reference(v7tbl) revised by Lorinda Cherry.

precise but technical, and the beginning user may prefer to read the examples first, as they show some common table arrangements. A section explaining how to invoke *tbl* precedes the examples. To avoid repetition, henceforth read *troff* as “*troff* or *nroff*.”

The input to *tbl* is text for a document, with tables preceded by a “.TS” (table start) command and followed by a “.TE” (table end) command. *Tbl* processes the tables, generating *troff* formatting commands, and leaves the remainder of the text unchanged. The .TS and .TE lines are copied, too, so that *troff* page layout macros (such as the memo formatting macros reference(latest msmacros)) can use these lines to delimit and place tables as they see fit. In particular, any arguments on the .TS or .TE lines are copied but otherwise ignored, and may be used by document layout macro commands.

The format of the input is as follows:

```
text
.TS
table
.TE
text
.TS
table
.TE
text
...
```

where the format of each table is as follows:

```
.TS
options ;
format .
data
.TE
```

Each table is independent, and must contain formatting information followed by the data to be entered in the table. The formatting information, which describes the individual columns and rows of the table, may be preceded by a few options that affect the entire table. A detailed description of tables is given in the next section.

2. Input commands.

As indicated above, a table contains, first, global options, then a format section describing the layout of the table entries, and then the data to be printed. The format and data are always required, but not the options. The various parts of the table are entered as follows:

2.1. Options

There may be a single line of options affecting the whole table. If present, this line must follow the .TS line immediately and must contain a list of option names separated by spaces, tabs, or commas, and must be terminated by a semicolon. The allowable options are:

```
center      center the table (default is left-
            adjust);
expand      make the table as wide as the cur-
            rent line length;
box         enclose the table in a box;
allbox      enclose each item in the table in a
            box;
doublebox   enclose the table in two boxes;
tab (x)     use x instead of tab to separate data
            items.
```

```
linesize(n) set lines or rules (e.g. from box)
              in n point type;
delim(xy)    recognize x and y as the eqn delimit-
            ers.
```

Tbl tries to keep boxed tables on one page by issuing appropriate *troff* “need” (.ne) commands. These requests are calculated from the number of lines in the tables, and if there are spacing commands embedded in the input, these requests may be inaccurate; use normal *troff* procedures, such as keep-release macros, in that case. The user who must have a multi-page boxed table should use macros designed for this purpose, as explained below under ‘Usage.’

2.2. Format

The format section of the table specifies the layout of the columns. Each line in this section corresponds to one line of the table (except that the last line corresponds to all following lines up to the next .T&, if any — see below), and each line contains a key-letter for each column of the table. It is good practice to separate the key letters for each column by spaces or tabs. Each key-letter is one of the following:

```
L or l      to indicate a left-adjusted column entry;
R or r      to indicate a right-adjusted column entry;
C or c      to indicate a centered column entry;
N or n      to indicate a numerical column entry, to
            be aligned with other numerical entries so
            that the units digits of numbers line up;
A or a      to indicate an alphabetic subcolumn; all
            corresponding entries are aligned on the
            left, and positioned so that the widest is
            centered within the column (see example
            on page 12);
S or s      to indicate a spanned heading, i.e. to indi-
            cate that the entry from the previous col-
            umn continues across this column (not
            allowed for the first column, obviously);
            or
^           to indicate a vertically spanned heading,
            i.e. to indicate that the entry from the pre-
            vious row continues down through this
            row. (Not allowed for the first row of the
            table, obviously).
```

When numerical alignment is specified, a location for the decimal point is sought. The rightmost dot (.) adjacent to a digit is used as a decimal point; if there is no dot adjoining a digit, the rightmost digit is used as a units digit; if no alignment is indicated, the item is centered in the column. However, the special non-printing character string \& may be used to

override unconditionally dots and digits, or to align alphabetic data; this string lines up where a dot normally would, and then disappears from the final output. In the example below, the items shown at the left will be aligned (in a numerical column) as shown on the right:

13	13
4.2	4.2
26.4.12	26.4.12
abc	abc
abc\&	abc
43\&3.22	433.22
749.12	749.12

Note: If numerical data are used in the same column with wider L or r type table entries, the widest *number* is centered relative to the wider L or r items (L is used instead of l for readability; they have the same meaning as key-letters). Alignment within the numerical items is preserved. This is similar to the behavior of a type data, as explained above. However, alphabetic subcolumns (requested by the a key-letter) are always slightly indented relative to L items; if necessary, the column width is increased to force this. This is not true for n type entries.

Warning: the n and a items should not be used in the same column.

For readability, the key-letters describing each column should be separated by spaces. The end of the format section is indicated by a period. The layout of the key-letters in the format section resembles the layout of the actual data in the table. Thus a simple format might appear as:

```

c  s  s
l  n  n .

```

which specifies a table of three columns. The first line of the table contains a heading centered across all three columns; each remaining line contains a left-adjusted item in the first column followed by two columns of numerical data. A sample table in this format might be:

	Overall title	
Item-a	34.22	9.1
Item-b	12.65	.02
Items: c,d,e	23	5.8
Total	69.87	14.92

There are some additional features of the key-letter system:

Horizontal lines — A key-letter may be replaced by

_ (underscore) to indicate a horizontal line in place of the corresponding column entry, or by = to indicate a double horizontal line. If an adjacent column contains a horizontal line, or if there are vertical lines adjoining this column, this horizontal line is extended to meet the nearby lines. If any data entry is provided for this column, it is ignored and a warning message is printed.

Vertical lines — A vertical bar may be placed between column key-letters. This will cause a vertical line between the corresponding columns of the table. A vertical bar to the left of the first key-letter or to the right of the last one produces a line at the edge of the table. If two vertical bars appear between key-letters, a double vertical line is drawn.

Space between columns — A number may follow the key-letter. This indicates the amount of separation between this column and the next column. The number normally specifies the separation in *ens**. If the “expand” option is used, then these numbers are multiplied by a constant such that the table is as wide as the current line length. The default column separation number is 3. If the separation is changed the worst case (largest space requested) governs.

Vertical spanning — Normally, vertically spanned items extending over several rows of the table are centered in their vertical range. If a key-letter is followed by t or T, any corresponding vertically spanned item will begin at the top line of its range.

Font changes — A key-letter may be followed by a string containing a font name or number preceded by the letter f or F. This indicates that the corresponding column should be in a different font from the default font (usually Roman). All font names are one or two letters; a one-letter font name should be separated from whatever follows by a space or tab. The single letters B, b, I, and i are shorter synonyms for fB and fI and refer to the bold and italic fonts in the current font family. Font change commands given with the table entries override these specifications.

Point size changes — A key-letter may be followed by the letter p or P and a number to indicate the point size of the corresponding table entries.

* One en is about the width of the letter ‘n’, or more precisely, half the current type size measured in points (1 point = 1/72 inch).

The number may be a signed digit, in which case it is taken as an increment or decrement from the current point size. If both a point size and a column separation value are given, one or more blanks must separate them.

Vertical spacing changes — A key-letter may be followed by the letter v or V and a number to indicate the vertical line spacing to be used within a multi-line corresponding table entry. The number may be a signed digit, in which case it is taken as an increment or decrement from the current vertical spacing. A column separation value must be separated by blanks or some other specification from a vertical spacing request. This request has no effect unless the corresponding table entry is a text block (see below).

Column width indication — A key-letter may be followed by the letter w or W and a width value in parentheses. This width is used as a minimum column width. If the largest element in the column is not as wide as the width value given after the w, the largest element is assumed to be that wide. If the largest element in the column is wider than the specified value, its width is used. The width is also used as a default line length for included text blocks. Normal *troff* units can be used to scale the width value; if none are used, the default is ens. If the width specification is a unitless integer the parentheses may be omitted. If the width value is changed in a column, the *last* one given controls.

Equal width columns — A key-letter may be followed by the letter e or E to indicate equal width columns. All columns whose key-letters are followed by e or E are made the same width. This permits the user to get a group of regularly spaced columns.

Staggered columns — A key-letter may be followed by the letter u or U to indicate that the corresponding entry is to be moved up one half line. This makes it easy, for example, to have a column of differences between numbers in an adjoining column. The `allbox` option does not work with staggered columns.

Zero-width item — A key-letter may be followed by the letter z or Z to indicate that the corresponding data item is to be ignored in calculating column widths. This may be useful, for example, in allowing headings to run across adjacent columns where spanned headings would be inappropriate.

Note: The order of the above features is immaterial; they need not be separated by spaces, except as indicated above to avoid ambiguities involving point size and font changes. Thus a numerical column entry in italic font and 12 point type with a minimum width of 2.5 inches and separated by 6 ens from the next column could be specified as

```
np12w(2.5i)fI 6
```

Alternative notation — Instead of listing the format of successive lines of a table on consecutive lines of the format section, successive line formats may be given on the same line, separated by commas, so that the format for the example above might have been written:

```
c s s , l n n .
```

Default — Column descriptors missing from the end of a format line are assumed to be L. The longest line in the format section, however, defines the number of columns in the table; extra columns in the data are ignored silently.

2.3. Data

The data for the table are typed after the format. Normally, each table line is typed as one line of data. Very long input lines can be broken: any line whose last character is \ is combined with the following line (and the \ vanishes). The data for different columns (the table entries) are separated by tabs, or by whatever character has been specified with the option `tabs`. There are a few special cases:

Troff commands within tables — An input line beginning with a . followed by anything but a number is assumed to be a command to *troff* and is passed through unchanged, retaining its position in the table. So, for example, vertical space within a table may be produced by `.sp` commands in the data.

Full width horizontal lines — An input line containing only `_` (underscore) or `=` (equal sign) is taken to be a single or double line, respectively, extending the full width of the table.

Single column horizontal lines — An input table entry containing only the character `_` or `=` is taken to be a single or double line extending the full width of the column. Such lines are extended to meet horizontal or vertical lines adjoining this column. To obtain these characters explicitly in a column, either precede them by `\&` or follow them by a space before the usual `tab` or `newline`.

Short horizontal lines — An input table entry containing only the string `_` is taken to be a single line as wide as the contents of the column. It is not extended to meet adjoining lines.

Repeated characters — An input table entry containing only a string of the form `\Rx` where x is any character is replaced by repetitions of the character x as wide as the data in the column. The sequence of x 's is not extended to meet adjoining columns.

Vertically spanned items — An input table entry containing only the character string `\^` indicates that the table entry immediately above spans downward over this row. It is equivalent to a table format key-letter of `^`.

Text blocks — In order to include a block of text as a table entry, precede it by `T{` and follow it by `T}`. Thus the sequence

```
... T{
    block of
    text
T} ...
```

is the way to enter, as a single entry in the table, something that cannot conveniently be typed as a simple string between tabs. Note that the `T}` end delimiter must begin a line; additional columns of data may follow after a tab on the same line. See the example on page 44 for an illustration of included text blocks in a table. If more than fifty or so text blocks are used in a table, various limits in the *troff* program are likely to be exceeded, producing diagnostics such as 'too many string/macro names' or 'too many number registers.'

Text blocks are pulled out from the table, processed separately by *troff*, and replaced in the table as a solid block. If no line length is specified in the block of text itself, or in the table format, the default is to use $L \times C / (N + 1)$ where L is the current line length, C is the number of table columns spanned by the text, and N is the total number of columns in the table. The other parameters (point size, font, etc.) used in setting the block of text are those in effect at the beginning of the table (including the effect of the `.TS` macro) and any table format specifications of size, spacing and font, using the `p`, `v` and `f` modifiers to the column key-letters. Commands within the text block itself are also recognized, of course. However, *troff* commands within the table data but not within the text block do not affect that block.

Warnings: Although any number of lines may be

present in a table, only the first 200 lines are used in calculating the widths of the various columns. A multi-page table, of course, may be arranged as several single-page tables if this proves to be a problem. Other difficulties with formatting may arise because, in the calculation of column widths all table entries are assumed to be in the font and size being used when the `.TS` command was encountered, except for font and size changes indicated (a) in the table format section and (b) within the table data (as in the entry `\s+3\fI\data\fp\s0`). Therefore, although arbitrary *troff* requests may be sprinkled in a table, care must be taken to avoid confusing the width calculations; use requests such as `.ps` with care.

2.4. Additional Command Lines

If the format of a table must be changed after many similar lines, as with sub-headings or summarizations, the `.T&` (table continue) command can be used to change column parameters. The outline of such a table input is:

```
.TS
options ;
format .
data
...
.T&
format .
data
.T&
format .
data
.TE
```

as in the examples on pages 43 and 46. Using this procedure, each table line can be close to its corresponding format line.

Warning: It is not possible to change the number of columns, the space between columns, the global options such as *box*, or the selection of columns to be made equal width. Nor is `.T&` recognized after the first 200 lines of a table.

3. Usage.

On UNIX® systems, *tbl* can be run on a simple table with the command

```
tbl input-file | troff
```

but for more complicated use, where there are several input files, and they contain equations and `-ms` layout commands as well as tables, the normal command

would be

```
tbl files... | eqn | troff -ms
```

and, of course, the usual options may be used on the *troff* and *eqn* commands. If any of the file names are - the standard input is read at that point.

For the convenience of users employing line printers without adequate driving tables or post-filters, there is a special -TX command line option to *tbl* which produces output that does not have fractional line motions in it.

Note that when *eqn* and *tbl* are used together on the same file, *tbl* should be used first. If there are no equations within tables, either order works, but it is usually faster to run *tbl* first, since *eqn* normally produces a larger expansion of the input than *tbl*. However, if there are equations within tables (using the *delim* mechanism in *eqn*), *tbl* must be first or the output will be scrambled. Users must also beware of using equations in n-style columns; this is nearly always wrong, since *tbl* attempts to split numerical format items into two parts and this is not possible with equations. The user can defend against this by giving the *delim(xx)* table option; this prevents splitting of numerical columns within the delimiters. For example, if the *eqn* delimiters are \$\$, giving *delim(\$\$)* a numerical column such as 1245\$+- 16\$ will be divided after 1245, not after 16.

Tbl accepts up to about 35 columns, the exact number depending on the availability of number registers. The user must avoid number register names used by *tbl*, which include two-digit numbers from 31 to 97, and strings of the form 4*x*, 5*x*, #*x*, *x*+, *x*|, ^*x*, and *x*-, where *x* is any lower case letter. The names ##, #-, and #^ are also used in certain circumstances. To conserve number register names, the n and a formats share a register; hence the restriction above that they may not be used in the same column.

For aid in writing layout macros, *tbl* defines a number register TW which is the table width; it is defined by the time that the .TE macro is invoked and may be used in the expansion of that macro. More importantly, to assist in laying out multi-page boxed tables the macro T# is defined to produce the bottom lines and side lines of a boxed table, and then invoked at its end. By use of this macro in the page footer a multi-page table can be boxed. In particular, the -ms macros can be used to print a multi-page boxed table with a repeated heading by giving the argument H to the .TS macro. If the table start macro is written

```
. TS H
```

a line of the form

```
. TH
```

must be given in the table after any table heading (or at the start if none). Material up to the .TH is placed at the top of each page of table; the remaining lines in the table are placed on several pages as required. Note that this is *not* a feature of *tbl*, but of the -ms layout macros.

4. Examples.

Here are some examples illustrating features of *tbl*. The symbol \oplus in the input represents a tab character.

Input:

```

5. Acknowledgments.

Many thanks are due to J. C. Blinn, who has done a large amount of testing and assisted with the design of the program. He has also written many of the more intelligible sentences in this document and helped edit all of it. All phototypesetting programs on UNIX are dependent on the work of the late J. F. Ossanna, whose assistance with this program in particular had been most helpful. This program is patterned on a table formatter originally written by J. F. Gimpel. The assistance of T. A. Dolotta, B. W. Kernighan, and J. N. Sturman is gratefully acknowledged.

6. References.
